(Received 7 July 2003; accepted 13 August 2003)

An expansion of the energy functional in terms of the total number of electrons and the normal coordinates within the canonical ensemble is presented. A comparison of this expansion with the expansion of the energy in terms of the total number of electrons and the external potential leads to new relations among common density functional reactivity descriptors. The formulas obtained provide explicit links between important quantities related to the chemical reactivity of a system. In particular, the relation between the nuclear and the electronic Fukui functions is recovered. The connection between the derivatives of the electronic energy and the nuclear repulsion energy with respect to the external potential offers a proof for the "Quantum Chemical le Chatelier Principle." Finally, the nuclear linear response function is defined and the relation of this function with the electronic linear response function is given. © 2003 American Institute of Physics.

I. INTRODUCTION

According to Density Functional Theory (DFT), the electronic energy of a many-electron system is given by

\[ E[\rho] = F[\rho] + \int \nu(\bar{r}) \rho(\bar{r}) d\bar{r}, \quad (1) \]

where \( F[\rho] \) is the universal Hohenberg–Kohn functional defined as the sum of the electronic kinetic energy functional, \( T[\rho] \), and the electron-electron interaction energy functional, \( V_{ee}[\rho] \), and \( \nu(\bar{r}) \) is the external potential that for an isolated molecule is just the potential due to atomic nuclei, but in general it may also include contributions from external fields or neighboring molecules. Minimization of the electronic energy with respect to the electron density with the constraint of constant total number of electrons, \( N \), leads to an Euler equation of the form

\[ \mu = \nu(\bar{r}) + \frac{\delta F[\rho]}{\delta \rho(\bar{r})}. \quad (2) \]

The solution to this equation yields the ground state electron density, from which one can determine the ground state energy.

Since the number of electrons and the external potential completely determine the Hamiltonian of the system, one can write the electronic energy of the system as a functional of \( N \) and \( \nu(\bar{r}) \) (i.e., \( E = E[N, \nu] \)). On the other hand, Eq. (1) establishes that \( E \) is a functional of \( \rho(\bar{r}) \) and \( \nu(\bar{r}) \) (i.e., \( E = E[\rho, \nu] \)). Differential expansion of the electronic energy, \( E \), for these two energy functionals allows us to determine the physical significance of the Lagrange multiplier, \( \mu \), which is found to be the electronic chemical potential of the system, that is,

\[ \mu = \left( \frac{\partial E}{\partial N} \right)_\nu. \quad (3) \]

and to find that the density is the functional first derivative of the energy with respect to the external potential at a constant total number of electrons, i.e.,

\[ \rho(\bar{r}) = \left( \frac{\delta E}{\delta \nu(\bar{r})} \right)_N. \quad (4) \]

Second-order derivatives of the energy with respect to \( N \) and \( \nu(\bar{r}) \) also have clear physical meanings. Thus, the second derivative with respect to the number of electrons at a fixed external potential \( \nu(\bar{r}) \) is the hardness:

\[ \eta = \left( \frac{\delta^2 E}{\delta N^2} \right)_\nu. \quad (5) \]

while the second derivative with respect to the external potential \( \nu(\bar{r}) \) at a fixed number of electrons is the linear response function.

\[ \Delta = \left( \frac{\delta^2 E}{\delta \nu(\bar{r})^2} \right)_N. \quad (6) \]

\[ \chi(\mathbf{r}, \mathbf{r}') = \left( \frac{\delta^2 E}{\delta \nu(\mathbf{r}) \delta \nu(\mathbf{r}')} \right)_N = \left( \frac{\delta \rho(\mathbf{r})}{\delta \nu(\mathbf{r}')}_N \right), \]

which measures the variation of the electron density at point \( r \) when the external potential of the system is locally perturbed at \( r' \). Finally, the Fukui function, first defined by Parr and Yang, is the second derivative with respect to external potential \( \nu(r) \) and the number of electrons,

\[ f(\mathbf{r}) = \left( \frac{\delta^2 E}{\delta N \delta \nu(\mathbf{r})} \right)_N = \left( \frac{\delta \rho(\mathbf{r})}{\delta \nu(\mathbf{r})}_N \right). \]

The Fukui function describes the local changes in the electron density of the system, due to the perturbation in the global number of electrons, so it reflects the character of a tron density of the system, due to the perturbation in the electronic chemical potential:

\[ \phi^+_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v = \tilde{F}_a(N+1) - \tilde{F}_a(N) = -\nabla_a E(N+1), \]

\[ \phi^-_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v = \tilde{F}_a(N) - \tilde{F}_a(N-1) = \nabla_a E(N-1), \]

\[ \phi^0_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v^0 = \frac{1}{2} (\tilde{F}_a(N+1) - \tilde{F}_a(N-1)) = \frac{1}{2} (\nabla_a E(N-1) - \nabla_a E(N+1)). \]

The last equality in Eqs. (12) and (13) is only valid when the \( N \) electron system of reference is at its equilibrium geometry \( \tilde{F}_a(N) = 0 \).

The second of these three approximations for the change in the electronic chemical potential:

\[ \phi_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v = -\left( \frac{\delta^2 E}{\delta N \delta \tilde{R}_a} \right)_N = -\left( \frac{\delta \mu}{\delta \tilde{R}_a} \right)_N. \]

From Eq. (15), three definitions of the NFF corresponding to the left, right, and central derivatives are also possible:

\[ \phi^+_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v^+ = \frac{\delta A}{\delta \tilde{R}_a} \equiv \frac{\delta \varphi}{\delta \tilde{R}_a}, \]

\[ \phi^-_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v^- = \frac{\delta I}{\delta \tilde{R}_a} \equiv \frac{\delta \varphi}{\delta \tilde{R}_a}, \]

\[ \phi^0_a = \left( \frac{\partial \tilde{F}_a}{\partial N} \right)_v^0 = \frac{1}{2} \left( \frac{\delta \mu_2}{\delta \tilde{R}_a} \right)_N = \frac{1}{2} \left( \frac{\delta \mu_1}{\delta \tilde{R}_a} \right)_N. \]

where the Koopmans' theorem has been used in Eqs. (16) and (17), and \( \mu_2 \) and \( \mu_1 \) in Eq. (18) refer to the following operational approximations for the electronic chemical potential:

\[ \mu_2 = -\frac{1}{2} (I + A), \]

\[ \mu_1 = -\frac{1}{2} (e_L + e_H). \]

It is remarkable the similarity between Eqs. (7) and (15). Geerlings and coworkers have computed NFFs for diatomic molecules using Eqs. (12) and (13), as well as from numerical calculations of the negative derivative of the chemical potential with respect to the atomic coordinates [Eqs. (16) and (17)] and with an approximate analytical method developed in analogy with Komorowski and Balawender's coupled Hartree–Fock approach to the electronic Fukui function. They have found that analytical and numerical results show a high correlation. Finally, it is worth mentioning that the relationship between the NFFs and the Berlin's binding
function\textsuperscript{13} has been recently discussed\textsuperscript{8,9,14} and new definitions of nuclear/geometric reactivity indexes have been also put forward.\textsuperscript{15–17} These studies\textsuperscript{8–12,14–17} have reinforced the idea that a complete representation of the total chemical response to a given perturbation must involve the analysis of both electronic and nuclear reactivity descriptors.

Because of the coupling between the electronic and nuclear responses to external perturbations, one can expect that relationships between nuclear and reactivity indexes exist. In the present paper we apply the general functional expansion scheme to expand the potential energy, $U$, and the total electronic energy, $E$, of the systems in terms of the total number of electrons, $N$, and normal coordinates displacements, $\{Q_k\}$, to derive relationships between electronic and nuclear indexes that connect the electronic and nuclear responses in front of a given perturbation. The energy expansion is carried out within the canonical ensemble, for which the natural variables are the global variable $N$ and the local variable $\nu(\vec{r})$.

II. ENERGY REPRESENTATIONS

In the Born–Oppenheimer approximation, the Potential Energy Surface (PES) of a system can be divided into an electronic ($E$) and nuclear repulsion ($V_{nn}$) energy terms as

$$U[\rho, \nu] = E[\rho, \nu] + V_{nn}[\nu].$$

(21)

As stated for the electronic energy, one can also write the PES of the system as a functional of $N$ and $\nu(\vec{r})$, i.e., $U = U[N, \nu]$:

$$U[N, \nu] = E[N, \nu] + V_{nn}[\nu].$$

(22)

A Taylor series functional expansion of the PES around a reference external potential $\nu_0(\vec{r})$ and total number of electrons $N$, retaining terms up to second order, acquires the form (note that the nuclear repulsion term does not depend on $N$)

$$\Delta U = \left( \frac{\partial E}{\partial N} \right)_\nu \Delta N + \int \left( \frac{\partial E}{\partial \nu(\vec{r})} \right)_N \Delta \nu(\vec{r}) d\vec{r}$$

$$+ \int \left( \frac{\delta V_{nn}}{\delta \nu(\vec{r})} \right)_N \Delta \nu(\vec{r}) d\vec{r} + \frac{1}{2} \int \left( \frac{\delta^2 E}{\delta^2 \nu(\vec{r})} \right)_N \Delta \nu(\vec{r}) d\vec{r}$$

$$+ \frac{1}{2} \int \int \left( \frac{\delta^2 V_{nn}}{\delta \nu(\vec{r}) \delta \nu(\vec{r}')} \right)_N \Delta \nu(\vec{r}) \Delta \nu(\vec{r}') d\vec{r} d\vec{r}'$$

$$+ \frac{1}{2} \int \int \left( \frac{\delta^2 E}{\delta \nu(\vec{r}) \delta \nu(\vec{r}')} \right)_N \Delta \nu(\vec{r}) \Delta \nu(\vec{r}') d\vec{r} d\vec{r}'$$

$$+ \int \left( \frac{\delta^2 E}{\delta \nu(\vec{r}) \delta N} \right)_N \Delta N \Delta \nu(\vec{r}) d\vec{r}.$$  

(23)

Equation (23) is the same used by Ayers and Parr to explore the effect that changing the external potential has on chemical reactivity.\textsuperscript{18} Now, substituting Eqs. (3) to (7) into Eq. (23) one finds that

$$\Delta U = \mu \Delta N + \int \rho(\vec{r}) \Delta \nu(\vec{r}) d\vec{r} + \int \left( \frac{\delta V_{nn}}{\delta \nu(\vec{r})} \right)_N \Delta \nu(\vec{r}) d\vec{r}$$

$$+ \frac{1}{2} \eta N \Delta^2 + \frac{1}{2} \int \chi(\vec{r}, \vec{r}') \Delta \nu(\vec{r}) \Delta \nu(\vec{r}') d\vec{r} d\vec{r}'$$

$$+ \frac{1}{2} \int \int \left( \frac{\delta^2 V_{nn}}{\delta \nu(\vec{r}) \delta \nu(\vec{r}')} \right)_N \Delta \nu(\vec{r}) \Delta \nu(\vec{r}') d\vec{r} d\vec{r}'$$

$$+ \Delta N \int f(\vec{r}) \Delta \nu(\vec{r}) d\vec{r}. \quad (24)$$

Let us now consider a molecule in an isotropic and homogeneous environment. In this case, the external potential depends only upon the relative nuclear positions. These relative positions can be specified using a set of $3N-6$ (or $3N-5$ for linear molecules) coordinates, the most natural choice being the use of the normal coordinates, $\{Q_k\}$. Given that the external potential for an isolated molecule can be defined from a set of $\{Q_k\}$ coordinates, one can write the energy of this system as a functional of $N$ and $\{Q_k\}$, i.e., $U = U[N, \{Q_k\}]$. In this functional form, a Taylor series expansion of the total energy up to second order yields

$$\Delta U = \left( \frac{\partial E}{\partial N} \right)_{\nu(Q_k)} \Delta N + \sum_{k=1}^{3N-6} \left( \frac{\partial U}{\partial Q_k_N} \right) \Delta Q_k$$

$$+ \frac{1}{2} \sum_{k=1}^{3N-6} \left( \frac{\delta^2 E}{\partial N \partial Q_k} \right) \Delta Q_k \Delta N,$$

(25)

$\Delta Q_k$ being the displacement of the normal mode $k$ from the equilibrium position. It is worth noting that since the external potential can be written as a function of the normal coordinates, it is possible to transform the derivatives with respect to the external potential to derivatives with respect to normal coordinates by using the chain rule. In this way, it is also possible to derive Eq. (25) from Eq. (23).

If we take as the reference state a molecule in its equilibrium geometry, then the term

$$\sum_{k=1}^{3N-6} \left( \frac{\partial U}{\partial Q_k} \right) \Delta Q_k,$$

(26)

in Eq. (25) and the term

$$\int \left( \frac{\delta U}{\delta \nu(\vec{r})} \right) \Delta \nu(\vec{r}) d\vec{r}$$

$$= \int \rho(\vec{r}) \Delta \nu(\vec{r}) d\vec{r} + \int \left( \frac{\delta V_{nn}}{\delta \nu(\vec{r})} \right) \Delta \nu(\vec{r}) d\vec{r},$$

(27)

in Eq. (24) are zero. We note in passing that Eq. (27) leads to the following interesting relationship that holds for an isolated molecule in its equilibrium geometry:

$$\left( \frac{\delta E}{\delta \nu(\vec{r})} \right) = \rho(\vec{r}) = -\left( \frac{\delta V_{nn}}{\delta \nu(\vec{r})} \right) N.$$

(28)
This equation is the result of the fact that, in the equilibrium geometry, the electronic energy change due to a perturbation in \(v(\vec{r})\) equals the negative of nuclear repulsion energy change, providing a relation between electronic and nuclear reactivity descriptors. Further, it is a nice proof to the first-order and within the framework of conceptual DFT\(^{19}\) of the “Quantum Chemical le Chatelier Principle” formulated by Mezey some years ago.\(^{20}\) This principle states that the electronic energy change induced by an external perturbation is compensated by a modification of the nuclear repulsion energy by a similar amount (in absolute value), in such a way that the value of the total energy (electronic + nuclear) is approximately conserved.

Now, from Eq. (25), using Eqs. (3) and (5) and taking into account that

\[
\left(\frac{\partial^2 E}{\partial N \partial Q_k}\right)_{v(\vec{r})} = -\left(\frac{\partial F_k}{\partial N}\right)_{v(\vec{r})} = -\phi_k \tag{29}
\]

and

\[
\left(\frac{\partial^2 U}{\partial Q_k} \right)_N = \lambda_k, \tag{30}
\]

one gets

\[
\Delta U = \mu \Delta N + \frac{1}{2} \eta \Delta N^2 + \frac{1}{2} \sum_{k=1}^{3N-6} \lambda_k \Delta Q_k^2 - \Delta N \sum_{k=1}^{3N-6} \phi_k \Delta Q_k. \tag{31}
\]

Equation (31) holds for a molecule in its equilibrium geometry. In Eqs. (29) and (31), \(\phi_k\) are the NFFs in terms of the normal coordinates and, in Eqs. (30) and (31), \(\lambda_k\) are the force constants of each normal mode.

A comparison of Eqs. (24) and (31) leads to Eqs. (32) and (34). Equation (32) is obtained, considering the independent terms with respect to \(\Delta N\):

\[
\frac{1}{2} \int \int X(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}' + \frac{1}{2} \int \int \chi(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}' = \frac{1}{2} \sum_{k=1}^{3N-6} \lambda_k \Delta Q_k^2, \tag{32}
\]

and defining the nuclear linear response function as

\[
X(\vec{r},\vec{r}') = \left(\frac{\partial^2 V_{nn}}{\partial v(\vec{r}) \partial v(\vec{r}')}\right)_N, \tag{33}
\]

while Eq. (34) appears matching the terms that depend on \(\Delta N\):

\[
\int f(\vec{r}) \Delta v(\vec{r}) d\vec{r} = -\sum_{k=1}^{3N-6} \phi_k \Delta Q_k. \tag{34}
\]

Equation (32) affords a relation for the nuclear and electronic linear response functions. For small \(\{Q_k\}\) displacements, the term \((1/2)\sum_{k=1}^{3N-6} \lambda_k \Delta Q_k^2\) in Eq. (32) gives the total change in the potential energy due to nuclear rearrangement. Equation (32) shows that this change can be decomposed in two parts: the first term, \((1/2) \int \int X(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}'\), represents the change of the nuclear potential energy due to the distortion while the remaining term is the change in electronic energy.

Equations (32) and (34) are the result of the Taylor series expansion of the PES functionals \(U = U(N,\nu)\) and \(U = U(N,\{Q_k\})\). Similarly, one can expand the functionals of the electronic energy \(E = E(N,\nu)\) and \(E = E(N,\{Q_k\})\). Following the same procedure one recovers Eq. (34) and also a modified version of Eq. (32) that reads as

\[
\frac{1}{2} \int \int \chi(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}' = \frac{1}{2} \sum_{k=1}^{3N-6} \lambda_k \Delta Q_k^2 - \frac{1}{2} \sum_{k=1}^{3N-6} \sum_{l=1}^{3N-6} \left(\frac{\partial^2 V_{nn}}{\partial Q_k \partial Q_l}\right)_N \Delta Q_k \Delta Q_l, \tag{35}
\]

Considering now the relation between the electronic energy and the PES given by Eq. (22), one obtains

\[
\frac{1}{2} \int \int \chi(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}' = \frac{1}{2} \sum_{k=1}^{3N-6} \lambda_k \Delta Q_k^2 \times \Delta Q_k \Delta Q_l. \tag{36}
\]

This equation provides a way to compute the \((1/2) \int \int \chi(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}'\) integral from the evaluation of the other two terms in Eq. (36). Remarkably, using Eqs. (36) and (32), it is possible to compute numerically all terms present in Eq. (24). By means of Eq. (24), one could carry out an energy decomposition analysis of the interaction between two given systems. More research on the value of such an energy decomposition analysis is underway in our laboratory.

Finally, from Eqs. (32) and (36) one obtains Eq. (37):

\[
\frac{1}{2} \int \int X(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}' = \frac{1}{2} \sum_{k=1}^{3N-6} \sum_{l=1}^{3N-6} \left(\frac{\partial^2 V_{nn}}{\partial Q_k \partial Q_l}\right)_N \Delta Q_k \Delta Q_l, \tag{37}
\]

which provides a means to numerically compute the \((1/2) \int \int X(\vec{r},\vec{r}') \Delta v(\vec{r}) \Delta v(\vec{r}') d\vec{r} d\vec{r}'\) integral.
connection between electronic and nuclear Fukui functions through a Taylor functional expansion of the energy as a functional of $N$ and $\{Q_i\}$.

### III. CALCULATION OF THE TERMS INVOLVED IN THE RELATIONS BETWEEN NUCLEAR AND ELECTRONIC REACTIVITY INDEXES

Throughout this paper we have assumed that all Taylor series converge. Moreover, we expect that if the external potential of the final system resembles that of the reference state sufficiently closely, low-order truncations of these functional Taylor series will be accurate. Our aim in this section is first to check this hypothesis by carrying out calculations of the two terms of Eq. (34). Second, the calculation of the \(\frac{1}{2} \int \chi(r, r') \Delta \nu(r') \Delta \nu(r') d^3 r d^3 r'\) and \(\frac{1}{2} \int \chi(r, r') \Delta \nu(r) \Delta \nu(r) d^3 r d^3 r'\) integrals will be performed for a series of diatomic molecules.

All calculations have been carried out with the GAUSSIAN 98 package at the Hartree–Fock (HF) level using the aug-cc-pVQZ basis set, except for the lithium atom, for which the cc-pVQZ has been used. The energy and gradient of the cationic and anionic doublet species has been computed within the unrestricted methodology at the geometry of the neutral systems, while the neutral singlet molecules have been calculated using the restricted formalism.

The numerical differentiation of $\varepsilon_{\text{HOMO}}$, $\varepsilon_{\text{LUMO}}$, $\mu_1$, $I$, $A$, and $\mu_2$ needed to evaluate Eqs. (16)–(18) has been carried out performing displacements of the equilibrium geometry of \(\pm (1,2,4,8,16,32,64) \times 10^{-n}\) (\(n = 2\) to 5) bohrs. Then, the smallest magnitude displacement that produced a stable derivative has been selected using a Romber method triangle.\(^{24}\)

Before starting the evaluation of the \(-\sum_{k=1}^{3N} \phi_k \Delta Q_k\) term in Eq. (34), we have checked for 13 diatomic molecules the consistency of the $\phi^+_i$, $\phi^-_i$, and $\phi^0_i$ nuclear Fukui functions calculated using the different approximations represented by Eqs. (12) to (14) and (16) to (18). The results obtained are listed in Table I. It is remarkable to see that calculations of the nucleophilic NFF, $\phi^+_i$, by numerical differentiation of $(\partial \varepsilon_{\text{HOMO}}/\partial R_a)_N$ and $(\partial \varepsilon_{\text{LUMO}}/\partial R_a)_N$ results in somewhat different numbers. The same is found for the electrophilic and radical NFFs. It is worth noting that the results obtained by Balabaner and Geerlings \(^{10}\) for $\phi^-_i$ and $\phi^+_i$ of H$_2$, LiH, BH, HF, HCl, $N_2$, $F_2$, CO, BF, and LiF at the HF/6-31+G** are, in general, in good agreement with those reported in Table I. As already pointed out by Baekelandt \(^8\) and Geerlings and coworkers,\(^{9,10}\) NFF data can be related to the Berlin's function,\(^8,13,14\) to analyze bonding in molecules. Thus, in diatomic molecules a positive nucleophilic NFF is associated to an increasing bond length upon the addition of an electron, which increases the total electron density in antibonding regions. All species studied show positive nucleophilic NFF as indicated by the values obtained from the $(\partial \varepsilon_{\text{HOMO}}/\partial R_a)_N$ and $(\partial \varepsilon_{\text{LUMO}}/\partial R_a)_N$ derivatives. Likewise, a negative electrophilic NFF is also related to an increase of the bond length during ionization, which means a reduction of the total electron density in bonding regions upon ionization. We found negative electrophilic NFF for all species studied, except for BH, $F_2$, CO, NF, and BF, for which positive electrophilic NFFs are obtained, indicating that the ionization should lead to a decrease of the bond length in these molecules.

Let us now numerically test the validity of Eq. (34). We have checked Eq. (34) for different displacements using the NFF obtained from Eqs. (12) to (14), although we only show in Table II the results for $\Delta Q = 1 \times 10^{-5} \times \sqrt[3]{\mu}$ a.u., where $\mu$ is the reduced mass, because with this displacement the error percentage becomes stable. We note that, from Eq. (8), the first term appearing in Eq. (34) is

\[
\varepsilon_{\text{HOMO}} - \varepsilon_{\text{LUMO}} = \mu_1 + I + A - \mu_2.
\]
The values of nuclear Fukui functions are obtained using Eqs. (12), (13), and (14). The $\Delta Q_k$ employed in all these cases is $1 \times 10^{-5} \times \sqrt{\mu}$ a.u., where $\mu$ is the reduced mass.

\[
\int f^+(\bar{r}) \Delta \nu(\bar{r}) d\bar{r} \\
= \int (\rho^{N+1}_{N+1}(\bar{r}) - \rho^{0}_{N}(\bar{r}))(\nu(\bar{r}) - \nu^{0}(\bar{r})) d\bar{r} \\
= \int \rho^{N+1}_{N+1}(\bar{r}) \nu(\bar{r}) d\bar{r} - \int \rho^{N}_{N}(\bar{r}) \nu^{0}(\bar{r}) d\bar{r} \\
- \int \rho^{0}_{N}(\bar{r}) \nu(\bar{r}) d\bar{r} + \int \rho^{0}_{N}(\bar{r}) \nu^{0}(\bar{r}) d\bar{r}, 
\]  
(38)

where $\rho^{N+1}_{N+1}(\bar{r})$ and $\rho^{0}_{N+1}(\bar{r})$ are the electron density at the equilibrium geometry for a system with $N$ and $N+1$ electrons, respectively, while $\nu^{0}(\bar{r})$ is the external potential at the equilibrium geometry and $\nu(\bar{r})$ is the external potential obtained increasing or decreasing the equilibrium bond length. The $\int \rho^{N+1}_{N+1}(\bar{r}) \nu^{0}(\bar{r}) d\bar{r}$ and $\int \rho^{0}_{N}(\bar{r}) \nu^{0}(\bar{r}) d\bar{r}$ integrals are explicitly the electron–nucleus potential energy of the system with $N+1$ and $N$ electrons at the equilibrium geometry, respectively. The $\int \rho^{N+1}_{N+1}(\bar{r}) \nu(\bar{r}) d\bar{r}$ and $\int \rho^{0}_{N}(\bar{r}) \nu(\bar{r}) d\bar{r}$ integrals in Eq. (38) are the electron–nucleus potential energy introducing the modified external potential $\nu(\bar{r})$, but using the $N+1$ and $N$ electronic density at the equilibrium geometry. All integrals present in Eq. (38) have been obtained from electron–nucleus potential energies computed with the GAUSSIAN 98 program.21,25 Equivalent expressions to Eq. (38) can be used to evaluate the integrals containing $f^+(\bar{r})$ and $f^0(\bar{r})$.

As can be seen in Table II, the difference between the first and the second term of Eq. (34) is usually quite small for all systems studied, and for the different nucleophilic, electrophilic, and radical approximations to the electronic and nuclear Fukui functions. The similarity between the values of the NFF computed using the two most reliable approximations makes us confident about the accuracy of the calculated NFFs, while operational equations that provide the electronic Fukui function [Eqs. (8) to (10)] are unavoidably approximate. Thus, in our opinion, the numerical errors that produce the differences observed may be larger in the computation of the integrals of the type $\int f(\bar{r}) \Delta \nu(\bar{r}) d\bar{r}$ than in the evaluation of the $-\sum_{k=1}^{N-6} \phi_k \Delta Q_k$ term. Figure 1 depicts the good correlation observed between the $\int f^+(\bar{r}) \Delta \nu(\bar{r}) d\bar{r}$ and the $-\sum_{k=1}^{N-6} \phi_k \Delta Q_k$ values giving an equation with a slope very

![Figure 1](image.png)
The calculation of the 
\[ \frac{1}{2} \int \nabla \psi \Delta \nabla \psi \, d\tau \] 
integral from the evaluation of the remaining two terms in Eq. (36) for the 13 diatomic molecules studied. All values are given in atomic units.\( ^a \)

\( ^a \) The \( \Delta Q_k \) employed in all these cases is \( 1 \times 10^{-5} \times \sqrt{\mu} \) a.u., where \( \mu \) is the reduced mass.

IV. CONCLUSIONS

In this paper, we have derived a set of connections among several nuclear and electronic indexes of reactivity in the framework of the conceptual Density Functional Theory by using an expansion of the energy functional in terms of the total number of electrons and the normal coordinates within a canonical ensemble. The relations obtained provide explicit links between important quantities related to the chemical reactivity of a system.

First, we have demonstrated that the derivative of the electronic energy with respect to the external potential of a system in its equilibrium geometry is equal to the negative of the nuclear repulsion derivative with respect to the external potential, giving a proof up to the first order for the so-called “Quantum Chemical le Chatelier Principle.” Second, following this particular approach, we have given an alternative proof the relation between the nuclear and the electronic Fukui functions, and, for the first time, we have numerically checked this relation. Finally, the nuclear linear response function has been introduced and a relation of this function with the electronic linear response function and the force constant has been provided.

25 The $\int \rho_{n+1}(\mathbf{r}) \nu(\mathbf{r}) d\mathbf{r}$ and $\int \rho_{n}(\mathbf{r}) \nu(\mathbf{r}) d\mathbf{r}$ integrals can be evaluated analytically with the GAUSSIAN 98 program using the keywords “massage” and “guess=read” to freeze the density at that of the equilibrium geometry and adding punctual charges to move nuclei to the new positions.
